ABSTRACT

This paper describes issues related to interactivity and access to underlying models and representations in system dynamics based learning environments. There is some evidence to suggest that system dynamics can be used effectively to promote understanding in complex domains (P. Davidsen, 1994, 1996; Sterman, 1988, 1997). However, there is insufficient evidence to establish whether this is in fact the case. Moreover, there has been little effort to address strategic design issues pertaining to the effective use of system dynamics in promoting learning in and about complex systems. This paper reviews relevant conceptual issues in promoting learner engagement with appropriate and relevant representations for complex domains. A unifying framework is used to describe a specific framework that provides opportunities for learner interactivity and that also capitalizes on learner access to explicit models and structures. This framework is illustrated in a simulation in which participants play the role of a leader in a multiple phase project for large-scale instructional development. TRANSPARENCY AND INTERACTION IN SYSTEM DYNAMICS BASED LEARNING ENVIRONMENTS

Abstract

The aim of this paper is to describe issues related to interactivity and access to underlying models and representations in system dynamics based learning environments. There is some evidence to suggest that system dynamics can be effectively used to promote understanding in complex domains (see, for example, Davidsen, 1994, 1996; Sterman, 1988, 1997). However, there is insufficient evidence to establish whether or not this is in fact the case. Moreover, there has been little effort to address strategic design issues pertaining to the effective use of system dynamics in promoting learning in and about complex systems. This paper is an attempt to review the relevant conceptual issues in promoting learner engagement with appropriate and relevant representations for complex domains. A specific approach will be presented and defended, an elaboration example will be discussed, and early evaluation results will be reported.

Interactivity, simulation-based learning, system dynamics

TRANSPARENCY AND INTERACTION IN SYSTEM DYNAMICS BASED LEARNING ENVIRONMENTS

Introduction

Technology enhanced learning environments are growing in number and prevalence at an unprecedented rate in spite of continuing debates in the academic literature with regard to their learning effectiveness, their impacts on organizations, and their overall utility to society (see, for example, Carter, 1997; Clark, 1994; Kozma, 1994; Lengel, 1997). As a consequence, there are many innovative investigations into how people might learn using new technologies, and these studies are, in turn, causing much discussion with regard to foundational issues in learning theory and instructional design.

As technologies have become more sophisticated, and as we have learned how to make effective uses of technology to promote learning in selected domains and situations, we have become more ambitious with regard to our hopes and expectations for technology enhanced learning and instruction. More specifically, we are attacking ever more challenging and complex domains as targets for improved learning through the use of technology, and such targets include environmental policy development

First, we briefly identify and review relevant learning theories. We then establish a unifying perspective in the context of these theories which has clear design and evaluation implications. This unifying perspective will then be used to describe a specific framework which provides extensive opportunities for learner interactivity and which also capitalizes on learner access to explicit models and structures. We conclude with an illustration of this framework and indicate other instances close in kind and spirit to ours.

Theoretical Perspective

How do people come to acquire complex skills and knowledge? We ask this apparently simple question in order to identify relevant assumptions and highlight its complexity. First, much learning research proceeds on the following assumptions:

1. Learning is a natural, human activity.
2. The unit of analysis for learning effectiveness is an individual human learner.
3. Learners are rational.

An additional assumption prevalent in the educational research community is that instructional design is primarily a prescriptive enterprise forming a bridge between descriptive learning research and practical development of learning environments (Reigeluth, 1983).

There is clearly practical value in adopting this research perspective. By varying the instructional methods used in certain conditions, one can measure outcomes and study the effects of those methods on learning outcomes. If enough data is collected, one then hopes to be able to establish

a strong argument for the desirability of a particular method given certain learning conditions, thus prescribing how one ought to design instruction to achieve desired outcomes. In this perspective, learning is a natural process, and it is theoretically possible to identify how various types of learners engage in this process and take those differences into account in the design of instruction. Learners are rational in the sense that they are goal-driven, purposeful agents with the ability to identify and select reasonably efficient means to achieve goals. Typically, conditions are held constant and various interventions (instructional methods instantiated in particular learning environments) are investigated. Learning outcomes or effects are then measured on individuals.

Such a research paradigm has in fact produced many useful findings, so it should not be discounted. For example, by emphasizing the rationality of learners, designers are able to facilitate the identification of learning goals and support activities likely to satisfy the achievement of those goals. This line of research emphasizes intentional learning, and generally ignores incidental learning, to which it is admittedly much more difficult to apply the conditions-methods-outcomes model. Since it is assumed that learners will want to achieve goals efficiently, designers can then specify how and when to provide learners with informative feedback on progress towards those goals.

We shall refer to this as the atomistic perspective because it is characterized by an atomistic view of learning, both in terms of units of learning (very specific and discrete conditions, methods, and outcomes) and in terms of learners (typically focusing evaluation on individual learners, even when the setting involves cooperative learning). The atomistic perspective can be contrasted with what we shall call the integrated perspective (Spector, 1994, 1995). The integrated perspective begins with a view of a person as a member of a society or language community. The overall goal of a society or language community typically involves a strong survival element, although this is quite often not made explicit. Living consists of working and learning, which are viewed as essentially collaborative efforts to achieve commonly held goals. From this perspective, individuals might manage to acquire extremely high levels of performance at particular tasks while the larger social group consistently falters. This would not count as effective learning from an integrated perspective.

There are definite comparisons to a team perspective when thinking of learning from an integrated perspective. A sports team may have several outstanding players, leading the league in certain categories, while the team is in last place. This is not a satisfactory situation, especially from the team's point of view. One can further imagine a team locked into poor overall performance by paying one star player an extremely large salary. This might prevent the team from paying higher salaries to others, and it may also foster jealousy and resentment within the team. While the star player may draw in large crowds and the team's owners may prosper, the team's poor performance may further decline, even when a second star player is added.

One should be careful not to carry the sports analogy too far, however. Learning organizations and societies are not necessarily competitive with other such organizations, as is the case in the world of sports. Moreover, membership criteria and reward mechanisms are entirely different. Our point here is to suggest that with many situations it is appropriate and useful to take a more

integrated, holistic view of learning. We believe this is especially important with regard to learning in and about complex domains.

Complex Domains

We are especially interested in complex domains for a number of reasons. From a research perspective, these domains present the most significant challenges, both for designing effective learning environments and for determining factors which contribute to learning. From a social perspective, these domains present the most significant challenges for the future well-being of our species on this planet. We have serious problems to confront if we are to survive, including worsening global environmental problems, persisting regional and ethnic conflicts, and wildly fluctuating economic conditions. Can we become better prepared to meet these challenges? How?

Complex systems can be depicted as a collection of inter-related items (e.g., stocks and flows in system dynamics), and they are characterized by internal feedback mechanisms, nonlinearities, delays, and uncertainties (Sterman, 1988, 1994). These systems typically exhibit dynamic behavior, especially in the sense that how they behave has an effect on internal relationships (the structure of the system), perhaps strengthening one of the feedback mechanisms (e.g., the owners' proceeds due to acquiring a star player reinforces that mode of response to declining profits, as opposed, for example to improving overall performance.). This change in internal structure in turn has consequences for how the system will behave in the future, for example, the team may perform even more poorly as existing players resent the special treatment and salary given the star (Davidsen, 1994, 1996).

Complex systems can be found in abundance at many different levels. The human body can be viewed as a complex system. Economics, ecology, epidemiology, project management, and training all typically involve complex, dynamic systems. As a species, we have well-documented difficulty in dealing effectively (understanding and making robust policies concerning) with such systems (see, for example, Dörner, 1996). There are clearly individual exceptions, persons who someone acquire a deep understanding of such systems. Typically, such deep understanding, characterized by effective decision making across a wide variety of changing conditions, takes years to acquire, and appears not to be easily acquired in spite of concentrated education and training efforts (Dreyfus & Dreyfus, 1986). Why have we failed to improve our thinking skills in complex domains in spite of such persistent and serious efforts?

In part, we have not fully understood relevant psychological and sociological factors. In part, we have not fully integrated relevant principles about human learning into design praxis. There are probably other factors, as well, but we shall hereafter focus on these two, especially the second.

We should have learned that humans have difficulty in estimating the effects of accumulation over time, in predicting the effects of delays, and in calculating nonlinear outcomes (Sterman, 1994). We should have learned that even well-intentioned persons tend to focus on local problems as opposed to whole systems (even when told that a holistic understanding is essential for solving particular problems), that people may become cynical and overlook possible solutions when their first attempts fail, that people do not communicate effectively in crisis

situations, and that inferring underlying system structures from externally viewed system behaviors is not an easy task (Dörner, 1996). Other overlooked lessons can and should be identified, but these provide some clear clues as to how we can return to theory and draw together relevant principles to guide the construction of learning environments for complex domains.

Theoretical Foundations

The theoretical foundations for this effort come primarily from socially-situated learning perspective, drawing heavily on the views of Bruner (1985), Lave (1988), Piaget (1970), and Vygotsky (1978), and from cognitive complexity theory (Spiro, et al. 1987). Within this perspective, learning is viewed as an active process of knowledge construction in which learners are typically involved with other learners in authentic, problem-solving situations. The need to learn created by a realistic problem provides motivation, and interaction with other similarly immersed learners provides facilitation. We are favorably inclined to an attitude similar Sford (1998) that emphasizes the need to take into account both an acquisition (static knowledge objects with learners acquiring expertise) and a participation metaphor (dynamic knowledge objects with learners as active apprentices). Much higher order learning relies on knowledge and associated learning activities that might best be supported within the acquisition view. However, to progress beyond competent performance and become a proficient expert (Dreyfus & Dreyfus, 1986), we believe that the participation metaphor with its emphasis on active learner participation in socially-situated and problem-oriented settings is crucial.

Socio-cultural theories of learning and teaching, as inspired by Vygotsky, have addressed the instructional use of computers. Some of these include situated learning (Lave, 1988), cognitive apprenticeship (Collins et al., 1989), learning by expanding (Engeström, 1987), scaffolding, cognitive artifacts, distributed cognition, and so on. In short, the theoretical heritage for technology enhanced learning is quite rich. Cognitive apprenticeship (Collins et al., 1989) has been the foundation for a number of very successful computer-based learning environments. These include *Sherlock* (Lajoie & Lesgold, 1989; Lesgold, Lajoie, Bunzo & Eggan, 1992) which made use of the concept of scaffolding where learners are provided with just enough assistance to help them construct their own answer to a problem, building on Vygotsky's notion of the zone of proximal development.

What seems most critical of all in technology enhanced learning environments is interactivity. This is a much addressed issue in the literature and we will not review that substantial literature here. Rather, we shall simply summarize what we believe are the relevant conclusions as follows:

- Doing goes hand-in-hand with learners; learners learn what they do.
- As learning environments provide more and more opportunities for active learner participation, they tend to promote learning; too many opportunities for interaction, however, can lead to confusion and disorientation.
- Cognitive engagement with the subject material is vital.
- Opportunities for reflection generally promotes learning.
- Informative feedback is a necessary part of a complete, cognitive engagement.

The next section of this paper discusses the implications of these theories and principles for the design of learning environments for complex domains.

Design Implications for Complex Domains

Sources of Complexity

It seems clear that the sources of complexity ought to be taken into account when designing support learning in and about complex systems. For example, if the source for complexity is the large number of variables involved, then ways to cluster and chunk these variable for learners will be important. On the other hand, if the source for complexity involves non-linear relationships of variables, then helping learners identify those non-linearities and associated effects is quite important. Likewise, when complexity is a consequence of delays in a system, then it is important to help learners identify those delays and their effects.

Some complexity may be the result of the inherent fuzziness of variables and relationships. Often associated with such uncertainties are the effects of human perceptions about a complex system. Again, it seems important to help learners identify those kinds of complexity and to determine their consequences. One important factor with regard to effects of human perception concerns the ability to determine things within the control of actors and agents within the system and those things beyond their control. Indeed, many decision makers mistakenly believe some things are beyond their control (Dörner, 1996).

Aids to understanding

Learner support should be responsive to the source of complexity. It should also be responsive to the needs of the learner. Allowing some learner control with regard to how much and what kind of help is provided is known to enhance learning in many situations (Collins, 1991). Moreover, providing less and less explicit support for learning is a powerful technique to enhance learning. Equally important to improving learning support is to offer multiple representations of various complex systems at different levels of aggregation (Sprio et al., 1987).

Overall outcomes of the intelligent tutoring research has led some to conclude that providing dynamic student modeling at a deep level and using that to determine what learning supports and materials to present to students remains a generally unresolved computational problem (Pea, 1993; Spector, 1994; Tennyson, 1993). A significant portion of the burden for determining how best to support learners is best left to learners. The various illustrations below demonstrate a variety of techniques for accomplishing this.

Transparency

Perhaps the single most important implication of the analysis of complex systems for the design of instruction concerns the relevance of underlying causal models for learning. Many previous instructional systems have been black box systems which kept the model hidden from learners. A

transparent approach provides learners with access to both the causal representation (e.g., a causal loop diagram) and the structural representation (e.g., a stock and flow diagram) of a complex system. This is entirely in keeping with principles of cognitive flexibility theory (Spiro et al., 1987). However, it introduces a new problem. These representations can become incredibly complex so the learner should be provided with appropriate chunks and provided opportunities to master those chunks (Davidsen 1994a, 1994b, 1996). Finally, it is important to insure that the learner has a clear picture of the overall system before proceeding to individual chunks or sectors (Spector & Davidsen, 1996, 1997a, 1997b).

An Elaborated Example

This example describes an interactive learning environment for practicing resource allocation in large scale instructional development projects. This learning environment contains a system dynamics based simulation model, which describes the structure and dynamics of large scale instructional development projects. The purpose of the learning environment is to develop users' appreciation and understanding of the many dynamic factors involved in project planning and resource allocation, especially those pertaining to how project teams are comprised. Such a learning environment allows managers and project participants to gain practice and experience -- an important factor for running projects successfully. It allows managers to compress time and learn from simulated situations by reflecting on the outcomes of decisions.

Instructional Systems Development (ISD)

Instructional systems development (ISD) is a reasonably well-structured and well-established process for developing educational and training systems and environments. Instruction often involves technology-based materials, often referred to as courseware. These systems involve significant and expensive software development and typically represent a level of complexity not encountered in more typical business-oriented software development projects. Large-scale courseware development projects often run behind schedule and over or beyond allocated budgets. They frequently use a lot of resources in terms of manpower, especially expertise that is already in scarce supply. There is clearly a delay associated with tasks having to be reworked, and failure to anticipate such a delay typically causes unexpected schedule overruns. There is also a relationship between how many tasks need to be reworked and the composition of the workforce (percent of experts and novices working on tasks). Experts typically provide better initial estimates of how large a project is and typically create fewer tasks requiring rework. Experts also cost more to keep on a project and are often in high demand and short supply. Such complex and dynamic factors as these make it difficult to determine optimal resource allocation for projects. How, then, can we promote the acquisition of these skills and knowledge?

We have chosen to use ISD⁴ (Tennyson, 1993) because it is consistent with system dynamics in that it explicitly recognizes internal feedback relationships and represents the system as dynamic as opposed to previous more static ISD models. Further, we focus on the allocation of expertise in the early stages of a large project, as things that go wrong here are more difficult to correct later.

The Purpose of the Learning Environment

The overall purpose of this learning environment is to develop an appreciation and understanding of the many dynamic factors involved in project planning and resource allocation, especially those pertaining to how project teams are comprised. The more specific goal is to help learners develop skills in formulating robust policies for distributed limited expertise across several large projects so as to keep the various projects on schedule and within budget. The target audience of this learning environment includes managers and project members in large scale ISD Projects. The target audience also includes people interested in resource allocation and project management in general, especially with regard to problems associated with scarce expertise and designing effective project teams comprised of both novices and experts. Prerequisite knowledge for learners includes familiarity with the basics concepts associated with project management (e.g., critical path analysis, project scheduling, etc.), system dynamics and system thinking (e.g., causal loop diagrams, internal feedback structures, etc.), and with ISD (e.g., requirements analysis, instructional design specification, etc.).

This learning environment has evolved from an earlier project to provide content specialists with a simulation authoring support tool for modeling continuous process systems, and it has been refined by a number of graduate students in the System Dynamics Masters Program at the University of Bergen (Sioutine et al. 1998; Spector, 1998; Spector & Davidsen, 1996).

The Simulation Model

We have been investigating resource allocation problems that arise in the context of ISD project management have been investigated using system dynamics theory (Forrester, 1961). The result of our research has been a system dynamics based model of ISD project development and management (Sioutine et. al., 1998). This model has been incorporated into a learning environment that is presented below. Note that the model is easily adjustable to institutional practices and should be refined and then validated to reflect what actually occurs within a particular organization. However, as with many models, there are key leverage points which dominate the system and generalize across a reasonably wide variety of organizational variations and local practices. Further, since we are focusing only on large scale instructional development, the assumption is that an organization engaged in such activities will have identifiable and established procedures and practices, since there will be strong interest in scalability, reuse, productivity, and related issues.

The model depicts the analysis and design phases, as these early stages are often the most crucial for a project in terms of ending up within time and budget constraints. Specifically, the attention is on the most common ways in which activities in these two phases are interrelated. These interrelated activities appear critical to resource allocation, planning, and to getting a project started on a productive path. Project phases can be generally described in terms of activities or work carried out by various project personnel. These activities are often described as tasks, where a task is considered a discrete piece of work or a specific activity with an associated work effort necessary for completion. Tasks, then, are identifiable and describable, having a more or less well-defined scope, usually measured in terms of person-days from the point of view of resource allocation.

The underlying model consists of four basic sectors that describe key aspects of the structure of the project: (1) human resource management; (2) control; (3) plans, and (4) development. A large part of the model is based on the work of Abdel-Hamid and Madnick (1990) applied to the modeling of the software project development. Figure 1 depicts the ISD model's major sectors with the main interrelationships between each of the sectors indicated by arrows.

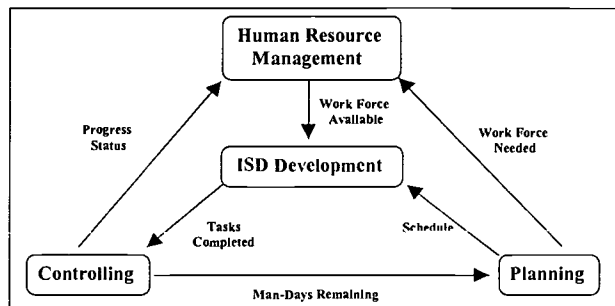

Figure 1. Sectors and interrelationships in an ISD model.

Analysis and design tasks can be described as passing through two stages: Identification and Processing. Tasks can be completed correctly (successfully) or incorrectly (unsuccessfully). Contrary to Abdel-Hamid and Madnick (1990), we have modeled the identification process explicitly, because identifying items is highly correlated with level of expertise, which we hypothesize is a central component of this system. Figure 1 represents a low level of transparency, as it does help develop deep insight into system behavior, but it does support understanding that the system is a whole with interrelated parts, and this understanding is a necessary building block in developing sensitivity to system behavior.

The diagram portrayed in Figure 2 represents the flow of tasks inside and between the analysis and design phases. Failed tasks eventually must be recognized and reworked. The tasks to be reworked can circulate inside a phase as well as between phases. The failure rate depends on the experience of the team, workforce composition and the general level of project know-how. The failure of a task means a failure of a discrete piece of work or activity, and this implies that it must be completed again, possibly effecting the completion or rework of other associated tasks. This represents a significant difference between software project modeling (where rework is described by errors in software code, and rework is dependent on the density of these errors) and instructional project modeling (where rework is described by failed tasks, and rework is dependent on the density of other tasks associated with the failed task). The success of rework in this formulation is a nonlinear function of the iteration process of tasks and project progress.

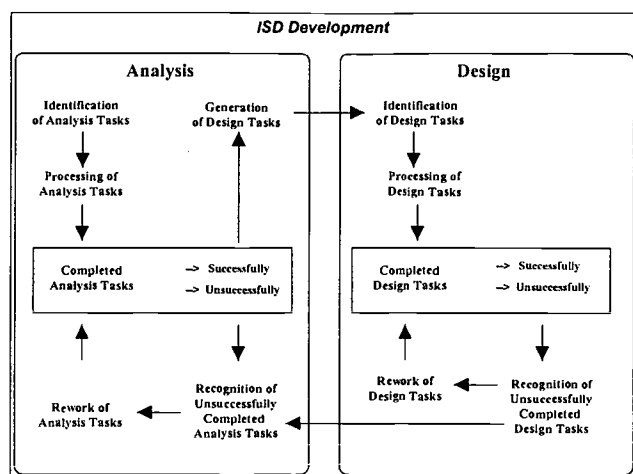

Figure 2. Interrelations in the analysis and design stages.

The sector that models human resource management consists of two sub-sectors: (1) the allocation of people to tasks and phases; and, (2) the hiring and transfer of people (Sioutine, 1998). The first sub-sector simulates the allocation (or release) of people on (from) different types of job based on the availability of workforce and resource requirements in different phases. The second sub-sector simulates the necessary hiring of people or transfer of people out of the project. The decisions for hiring or transfers are based on the workforce sought in order to complete the project on time. That information comes from the control and planning sectors. The workforce is differentiated into two types: experts and novices. As a consequence of the different types of workforce, the productivity of an average person in the project team will be lower than the potential productivity of the team (Abdel-Hamid & Madnick, 1989; Steiner, 1972).

The structure of the model portrays how complex the project management problem is. Therefore, the aim of the learning environment based on this model is to show just enough complexity to demonstrate to learners the key relationships between the structure and the behavior of the system, enabling them to better constitute teams within the early and critical phases of a large project.

The Structure of the Learning Environment

The “On Time, Within Budget” Learning Environment is a collaborative, simulation-based learning environment. It has an underlying model of key project management problems, specifically aimed at representing the analysis and design phases of large instructional development projects. It has been designed to be played in a local area network with three computers (one for each player) and a server. It is possible to play as a team, each team playing one of the the roles designed in the game, or one person can play one of the roles on a single computer with the other roles being simulated by the computer. Because small groups or teams are encouraged, the game is intended as a collaborative learning environment, even though it is possible for individuals to learn in isolation from other learners.

This learning environment situates players in a simulated replica of a real project. It is interactive, because players are required to intervene, design strategies, implement strategies, observe results. Players also receive feedback regarding their performance, and they have the chance to offer comments at several stages within an activity. The overall design approach used in this environment is based on cognitive apprenticeship (Collins, 1991), on socially situated learning (Lave, 1988), and on graduated complexity as the primary elaboration sequence (Reigeluth, 1983). The notion of graduated complexity in the environment is implemented in such a way that users can explore a problem on several levels of complexity, getting more sophisticated information at each of the subsequent levels. The whole problem of management is separated into several sub-structures: human resource allocation, time planning, process development information, personnel information and progress perceptions. Each of these structures are represented in the form of an information or decision desk, whereupon the learner can choose to get more information regarding that substructure.

This environment has been designed in such a way that players are first presented with a simple representation of information. For example the representation of tasks is symbolised as a kind of pile (e.g., pile of papers). The player will normally be given initial information and can then optionally explore the problem on three additional levels of complexity, suggested by the environment and appropriate to the specific context. Each level provides learners with more detailed information on key structural relationships. The general scheme is that at the first level learners get information concerning what is being influenced by their decision(s), or what is influencing that particular decision point. At the second level, participants get causal and/or structural relationships, usually provided with a pop-up causal loop diagram.

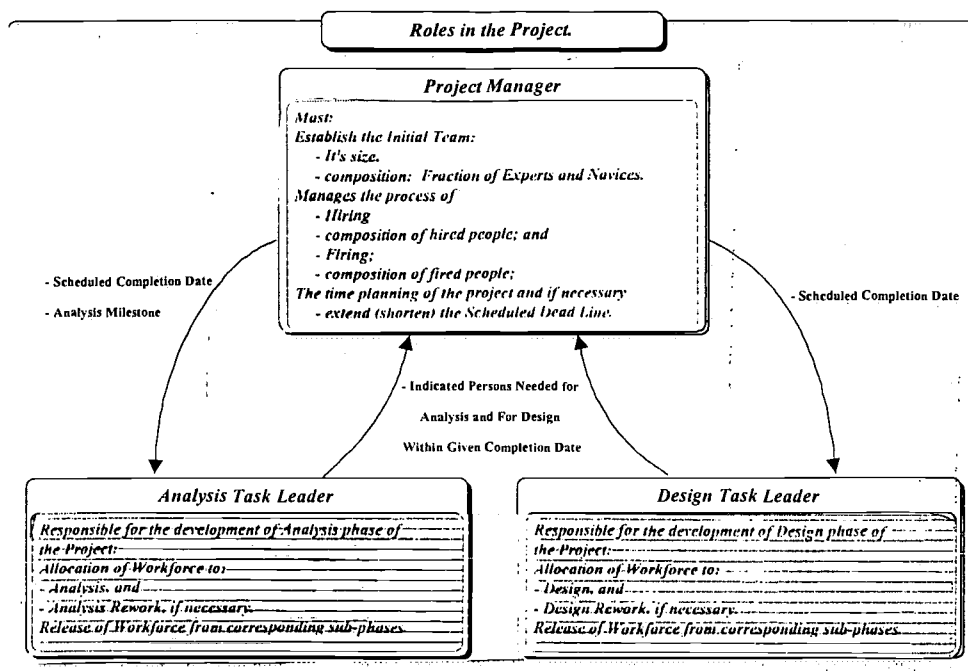

Figure 3. Roles, responsibilities and interactions in the project.

Finally, at the third level learners will get a simplified structure in terms of a stock and flow diagram. At each level learners have the possibility to obtain information about the behavior of the system in the form of graphs. This provides learners with a fundamental representation of key structural-behavioral interrelationships in the system. During interactions with the simulation environment, learners are asked to record their rationale for decisions on the decision record sheets. They are asked to record each decision at each particular point and also asked to answer this question: "Why did you make this a decision?"

Dörner's (1996) research indicates that providing opportunities for reflection contributes to improved learning. As a consequence, learners have to provide at least one short sentence indicating why a particular decision was made. This enforced pause for reflection also provides a key opportunity for small group interaction, consistent with the collaborative nature of the learning environment. While this pause may seem like an additional burden for the learners, it in fact provides them with essential opportunities for collaboration and reflection, and avoids the impression that they are just manipulating parameters. The expectation is that learners will eventually gain an appreciation for and understanding of the complexities of the system. Learners can also record alternative decisions that could have been made at some point and some comments on why that decision was not accepted.

Description of Roles

In this learning environment participants play the role of one of the leaders of a multiple phase project for large-scale instructional development. The phases of the project involved are the early project planning phases of analysis and design. The task for the players will be to allocate resources, especially limited expertise, so as to keep the project on time and within budget. They will have an opportunity to practice various resource allocation policies in an attempt to find a policy, which avoids catastrophic results (late and costly projects). There are

three basic roles in the project game to be played: Project Manager, Analysis Task Leader, and Design Task Leader.

The relationships and responsibilities of each of them are portrayed in Figure 3.

Project Manager. The project manager is the one who controls the pool of workforce in the project, does the time planning and sets the completion date for the project. This person is responsible for establishing the initial team and its composition in terms of workforce mix, and is also responsible for hiring additional people or transferring people from the workforce pool. The project manager has to foresee future needs so that there will be enough workforce to complete the development. On the other hand, if persons are staying in the pool of available workforce but not assigned to any tasks, these persons are standing by, waiting, and are paid for being in the project, driving project costs up without associated improvements in productivity. The decisions to be taken by the project manager are:

- how many persons to hire or transfer during the coming decision period;
- what mix of people to have in terms of percentage of experts and novices; and,
- set the deadline for the project and the milestones for the phases.

The allocation policy that participants are currently provided is the simplest one (SAY WHAT THAT POLICY IS !!!). While other types of policies are implemented in the model (e.g., top priority goes to the rework of tasks), the principles of cognitive apprenticeship and graduated complexity suggest that learners should start with a simple allocation policy first.

Analysis Task Leader. The analysis task leader is the leader of the analysis phase of the project. This person (or group) is responsible for completion of analysis by allocating resources to support analysis and associated rework. This leader and the task leader of the design phase are going to use and compete for the workforce resources from the common pool of persons available. The leader must eventually learn to keep in mind that it is possible to reallocate resources for example from analysis to analysis rework only by releasing workers from one sub-phase and making them available in the persons available pool. It is then up to the project manager to decide whose requests to satisfy first. The project manager makes this decision so that people will be allocated (assigned new job) and sent to one of the phases or sub-phases according to the prioritisation that the manager has. Separating these decisions and roles forces learners to develop reasonably sophisticated justifications for resource allocation and assignment of scarce expertise to specific tasks and phases.

Design Task Leader. The design tasks leader is the leader of the design phase of the project. This person is responsible for completing the design phase by allocating resources to design and associated design rework. This leader is in the same kind of situation as the leader of analysis. The leaders of the two phases have to collaborate with each other in order to use the resources most effectively. Since there is an interaction and iteration of tasks between the phases, at some points it may be necessary to do more of the design in order to discover flaws of analysis, so that both phases can proceed further. Therefore, at such moments in the design phase. This is the challenge that participants are facing in this learning environment. The decisions to be taken by the analysis and design tasks leaders include the following:

- How many persons to request for the coming decision period for processing regular analysis or design tasks.
- How many persons to request for the coming decision period for processing rework analysis or design tasks.
- How many persons can be released from processing of regular analysis or design tasks during the coming decision period.
- How many persons can be released from rework of analysis or design tasks during the coming decision period.

Learning in This Environment

At the very beginning of the learning experience with the simulator, learners are provided with information about their roles and responsibilities, and the requirements of their positions. The players are asked to keep the project on time while minimizing costs. In reality, the situation is more complicated since quality is a highly critical factor and would also have to be taken into consideration. Consistent with the notion of graduated complexity, however, this environment emphasizes minimizing costs while still delivering an acceptable end product on schedule. A more sophisticated goal could be to deliver the highest quality product without significant cost and time overruns, but that is not the learning goal here.

Referring to the diagram of the project structure in Figure 1, the management of a project involves several dynamically interrelated structures. Without looking much deeper it is already obvious that the resource allocation situation is complicated, and as we take a deeper look into project dynamics, it will become even more complicated. Appreciating and understanding this complexity is one of the learning objectives of this simulator.

To complete the project the players have to complete both phases. At the beginning, there is some estimate of the project size in terms of analysis and design tasks. This estimate may be different from the real size at the beginning, and, therefore, will need to be adjusted as simulation proceeds through the development of the project. The priority for allocation of people initially is that people are first allocated to Analysis, then to Analysis Rework, then to Design, and finally to Design Rework. Therefore, if there are multiple requests for allocations to different sub-phases (e.g., regular Analysis or Analysis Rework, or regular Design and Design Rework), first priority will be to satisfy requests for allocation to regular analysis, then to analysis rework, then to regular design, and finally to design rework. Later allocations to subsequent sub-phases are made depending on the availability of workforce in the pool of Persons Available.

Figure 4. An example of the Main Office screen for the Design Task Leader.

The project learning environment was designed to be installed in a computer network with three local computers and a server. This is an asymmetric game, with different persons/teams playing different roles and making different decisions. The common goal is to complete the project on time and within budget. Each player/role has its own interface representing the corresponding role to be played. However, each of the interfaces are similar in the representation of the information and metaphors that represent certain concepts.

The way the project learning environment proceeds is that players are initially provided with information about the project environment, its characteristics, the aims and prerequisites for "On Time, Within Budget," and how to navigate, get information, and make decisions. Thereafter, players can optionally

- get help on navigation;
- ask for the project description;
- get information on the project structure; or,
- ask for a role description.

The players then enter the project environment based on the role that has been selected or determined by the facilitator. Players are allowed two choices:

- Play With Computer; or,
- Play Together With Other Players.

The first choice allows players to run the project in the role that has been described in the introduction section in "collaboration" with other players simulated by the computer. That is, the other two roles will be simulated according to the policy and decision structure built into the

underlying model for the corresponding roles. The second choice involves all of the players as real persons/groups playing each role on different computers.

For the purpose of practice and familiarization, it is suggested that players first play with the computer simulating the other roles, as the need to collaborate with those playing the other roles is an additional level of complexity. After learners have gained familiarity with the environment, they are prepared to initiate a collaborative game. It is also recommended that all learners eventually play each of the different roles in order to get an appreciation of the problems associated with that role and the possible misperceptions of others involved in the decision process.

The metaphor underlying “On Time, Within Budget” consists of the idea that users are in a virtual office. From that place they can get to the areas of interest through doors leading to a corresponding place. Once players start the project they are placed into their *MAIN OFFICES*. This place connects them to all of the information sources that they have in the project learning environment. The layout of the *MAIN OFFICE* is exhibited in Figure 4. From the “Main Office” players can chose the following areas, by following in to the corresponding door:

- **DECISION DESK:** the decisions and assumptions can be tested and then implemented.
- **SCHEDULE DESK** for the project manager and **CALENDAR** for the task leaders. At **SCHEDULE DESK**, the project manager sets the completion date and analysis milestone. At **CALENDAR**, the two phase leaders receive the information about the completion date and time remaining.
- **PERSONEL INFORMATION:** the information about the workforce level, productivity and time utilization.
- **PROGRESS REPORT:** provides the information about project accomplishment and resources used.
- **TASKS/JOB INFORMATION:** provides the information about work load on different stages of the project’s phases (identification, processing, rework recognised, rework, accomplishment)

The Two Modes of Interaction: Decision and Strategic

During the interaction with the learning environment players will have the possibility to run the simulation in two modes: strategic and decision. The strategic mode (or Try Decisions) allows players to test decisions, before accepting them into the project. This allows plays to try out diverse strategies for each of the scenarios, therefore giving players the chance to look into the future and evaluate the possible impacts of their decisions. These trial decisions are not submitted to other players/teams but are only tested locally and discussed by a particular team as a possible strategy to pursue. For this reason, players have to make assumptions about the decisions of the other teams. This possibility is provided at the “DECISIONS” desk by the “TEST ASSUMPTIONS” option. This brings up the “ASSUMPTIONS” panel where players are provided with virtual control over the decision variables of the two other players. After players have tested enough strategies and made up their minds, they are ready for switching to the Decision Mode by choosing “Revert to Game” option on the game control panel. The players

will then be asked if they want to keep the current decisions or not. Finally, when a team is ready to make decisions, they chose “Accept Decisions,” which will deliver decisions to the other players. As soon as everybody is ready with their decisions, the project will proceed further and players will soon get another request for their decisions.

The players are asked to make their decisions every 10 days, and submit them when they are asked for. However, the decision interval can be changed by the facilitator. The project runs until its completion or until it falls behind schedule, which means that a team was not able to complete the project within the scheduled deadline. As the simulation unfolds the players will eventually get feedback on their performance and the state of the project. This messages are designed to gain the attention of the players. For example, when the project management team perceives that a projects falls behind schedule and requires overtime and rework, a message appears indicating that the workforce is about to become exhausted. Suggestions with regard to possible actions are available (e.g., review the schedule of the project, or add more people, etc.).

Findings

Learning is a feedback process which has several barriers that prevent successful outcomes in complex dynamic systems (Dörner, 1996; Sterman, 1994). These barriers include the complexity of the system itself, the future and possibly delayed effects of decisions, and various non-linear and somewhat uncertain relationships within the system. The use of simulation-based learning environments allows for compressing dynamics that would otherwise take place over long time periods, thereby overcoming some traditional barriers to successful learning in this domain. The “On Time, Within Budget” Learning Environment presented in this paper provides a laboratory tool for learning and practising the management of complex project management skills, particularly resource allocation and planning project schedules and milestones.

A special concern during the design of this learning environment was also given to the translation of the external instructional events described by Gagné (1995). These learning events are as follows: gaining attention, informing of the objective, stimulating recall of prior knowledge, presenting information and content, providing “learning guidance,” eliciting performance, providing feedback, assessing performance and enhancing retention and transfer. A certain degree of transparency for the learner is achieved by representing structural relationships using feedback loop diagrams and structural diagrams. These provide learners with a representation of the model structure and allow for better understanding of the structural-behavioral relationships existing in the system. (Davidsen 1994).

The learning environment presented in this paper offers a tool for practicing resource allocation in project management. This environments facilitates learning and transfer of the knowledge about the existing problems using an underlying system dynamics model and simulation. It portrays general ideas and problems of project management. Therefore, it can be used not only for instructional projects but for other types of projects as well. The next step in the development of the instructional material would be an integration it with the other components of the Bergen project, which provide tutorials in the areas of project management, instructional development, system dynamics and system thinking. Such an effort would produce a highly engaging virtual micro-world for resource allocation in large scale instructional projects.

Our investigations into black-box learning environments shows that there is inadequate learning support and that learning outcomes are marginal. Moreover, investigations in the effects of understanding specific issues associated with complex domains (e.g., recognizing and predicting effects of second order delays) indicates that providing learners with access to underlying models, along with opportunities to perform both hypothetical strategy formulation and active decision making in a realistic setting, can produce learning benefits (Bahaa et al.,).

Concluding Remarks

It is premature to argue that a framework such as the one presented here will produce significant, long-lasting, and positive learning effects in and about complex systems. Based on existing data collected on our learning environments and from data reported on some of those which adopt similar approaches, we believe that there is great promise in designing collaborative telelearning environments from a socially-situated learning perspective with heavy emphasis on collaborative learner participation in the creation and modification of knowledge objects and artifacts. We look forward to learning about the results and findings of others in this area.

We have reported some of our findings at meetings of the International System Dynamics Society (Sioutine, Davidsen, & Spector, 1998; Spector & Davidsen, 1997b), and we have been encouraged to learn that the system dynamics community is coming around to the view that it is not generally sufficient to provide only behaviorally oriented feedback about complex systems if one wishes to promote deep understanding of such systems. Learners should be encouraged to engage in model alteration, model construction, and policy and strategy design in a collaborative context if one expects lessons to transfer from the learning environment to real-world settings. In addition, we have presented this framework to the Competence-Based Management Conference (Spector, 1998), and we are encouraged to learn that this approach appears relevant to the teaching of skills and expertise pertaining to management.

REPRODUCTION RELEASE

(Specific Document)

I. DOCUMENT IDENTIFICATION:

Title: <u>Transparency and Interachyn on System Dynamics Based Learning Environment</u>	
Author(s): <u>J. MICHAEL SPECTOR & P.H. Davidsen</u>	Publication Date: <u>21 Apr 1999</u>
Corporate Source: <u>University of Bergen</u>	

II. REPRODUCTION RELEASE:

In order to disseminate as widely as possible timely and significant materials of interest to the educational community, documents announced in the monthly abstract journal of the ERIC system, *Resources in Education* (RIE), are usually made available to users in microfiche, reproduced paper copy, and electronic media, and sold through the ERIC Document Reproduction Service (EDRS). Credit is given to the source of each document, and, if reproduction release is granted, one of the following notices is affixed to the document.

If permission is granted to reproduce and disseminate the identified document, please CHECK ONE of the following three options and sign at the bottom of the page.

The sample sticker shown below will be affixed to all Level 1 documents

PERMISSION TO REPRODUCE AND DISSEMINATE THIS MATERIAL HAS BEEN GRANTED BY _____ Sample _____ TO THE EDUCATIONAL RESOURCES INFORMATION CENTER (ERIC)

1

Level 1

Check here for Level 1 release, permitting reproduction and dissemination in microfiche or other ERIC archival media (e.g., electronic) and paper copy.

The sample sticker shown below will be affixed to all Level 2A documents

PERMISSION TO REPRODUCE AND DISSEMINATE THIS MATERIAL IN MICROFICHE, AND IN ELECTRONIC MEDIA FOR ERIC COLLECTION SUBSCRIBERS ONLY, HAS BEEN GRANTED BY _____ Sample _____ TO THE EDUCATIONAL RESOURCES INFORMATION CENTER (ERIC)
--

2A

Level 2A

Check here for Level 2A release, permitting reproduction and dissemination in microfiche and in electronic media for ERIC archival collection subscribers only

The sample sticker shown below will be affixed to all Level 2B documents

PERMISSION TO REPRODUCE AND DISSEMINATE THIS MATERIAL IN MICROFICHE ONLY HAS BEEN GRANTED BY _____ Sample _____ TO THE EDUCATIONAL RESOURCES INFORMATION CENTER (ERIC)
--

2B

Level 2B

Check here for Level 2B release, permitting reproduction and dissemination in microfiche only

Documents will be processed as indicated provided reproduction quality permits.
If permission to reproduce is granted, but no box is checked, documents will be processed at Level 1.

Sign here, please

I hereby grant to the Educational Resources Information Center (ERIC) nonexclusive permission to reproduce and disseminate this document as indicated above. Reproduction from the ERIC microfiche or electronic media by persons other than ERIC employees and its system contractors requires permission from the copyright holder. Exception is made for non-profit reproduction by libraries and other service agencies to satisfy information needs of educators in response to discrete inquiries.
